Abstract

Introduction

The two broad subcategories of neuroendocrine neoplasms (NENs) are well-differentiated neuroendocrine tumors (WDNETs) and poorly differentiated neuroendocrine carcinomas (PDNECs), based on tumor architecture and cytology. Grade 3 WDNETs are a subset of WDNETs that not only are high grade by mitotic activity or proliferative index but exhibit a well-differentiated histology. In this study, we evaluated the clinicopathological features of primary neuroendocrine tumors of the gastrointestinal (GI)/pancreatobiliary tract with emphasis on high-grade WDNETs, as it is a newly defined entity.

Methods

We conducted a retrospective observational study, including a total number of 122 cases of primary GI and pancreatobiliary tract NENs. Slides and blocks of all cases were retrieved from the departmental archives. Immunohistochemical stains including Ki67 were applied to selected tissue blocks of all cases. Tumors were then evaluated for their histological differentiation and tumor grade.

Results

Our results showed that the mean age of patients was 46.8 ± 17.1 years. Majority of the NENs were GI tract origin (86.9%). The most common site of tumor in gastroenteropancreatic tract was the small bowel (31.1%), followed by the stomach (26.2%). Ninety five percent of the tumors were WDNETs, of which the most common grade was G2. The mean Ki67 index was 15.8 ± 23.8 . Grade 3 WDNETs were noted to have an older mean age than grades 1 and 2 WDNETs. Ten out of 102 (9.8%) WDNETs of GI tract were grade 3, compared with four out of 14 (28.6%) of pancreatobiliary tract.

Conclusion

In this study, we found that high-grade (grade 3) WDNETs were more frequent in pancreatobiliary tract than GI tract. Moreover, high-grade WDNETs were associated with a higher mean age than low-grade (grade 1-2) WDNETs. It is extremely important to recognize this subset (high grade) of WDNETs and to distinguish it from PDNECs, as the latter are known to be associated with a worse overall survival. Despite high mitotic rate/proliferative index, high-grade WDNETs are characterized by organoid architecture and monomorphic cell population.

Introduction

Neuroendocrine neoplasms (NENs) are indolent tumors that can arise in almost all organ systems of the body and encompasses a diverse range of clinical, morphological, and genomic features with varied outcomes. They tend to arise from neuroendocrine cells, i.e., cells having characteristics of both nerve cell

(ability to receive signals from the nervous system) and endocrine cells (ability to secrete hormones and peptides) [1]. Histologically, NENs are subclassified into low-proliferating well-differentiated neuroendocrine tumors (WDNETs) and high-proliferating poorly differentiated neuroendocrine carcinomas (PDNECs) [2].

The large magnitude of the gasteoenteropancreatic tract puts it as the most common site of origin for NENs, followed by lungs [3]. They constitute 2% of the malignant tumors of the gastroenteropancreatic tract [4]; however, due to the endoscopic screening and early detection, their incidence has increased in the past decades [5].

According to the fifth edition of the World Health Organization (WHO) Classification of Digestive Tumors, NENs are classified into WDNETs grade G1, G2, and G3 as well as neuroendocrine carcinomas (NECs), which constitute the poorly differentiated tumors. NECs are further subclassified into small-cell neuroendocrine carcinomas (SCNECs), large-cell neuroendocrine carcinomas (LCNECs), and finally the mixed neuroendocrine-non-neuroendocrine neoplasms (MiNENs), which are mixed epithelial neoplasms in which a neuroendocrine component is combined with a non-neuroendocrine component. This classification is based on tumor grading done by virtue of the mitotic activity and the Ki67 proliferative index [3].

The term well-differentiated, in the context of NENs, denotes the strong resemblance of tumor cells to the non-neoplastic neuroendocrine cells by virtue of their immunopexpression of general neuroendocrine markers (chromogranin A and synaptophysin) and peptide hormone production.

Grade 3 WDNETs are a subset of WDNETs, which are high grade by mitotic rate or proliferative index and exhibit a well-differentiated histology. They have a prognosis that is somewhere between the Grade 2 WDNETs and PDNECs, former being more indolent. In this study, we evaluated the clinicopathological features of primary neuroendocrine tumors of the gastrointestinal (GI)/pancreatobiliary tract with emphasis on high-grade WDNETs, as it is a newly defined entity.

Materials And Methods

We conducted a retrospective observational study at the Department of Histopathology, Liaquat National Hospital and Medical College, Karachi. A total number of 122 cases of primary GI and pancreatobiliary NENs were retrieved from the departmental archives from January 2011 until July 2020. Cases with prior history to chemoradiation were excluded from the study along with cases of metastatic neuroendocrine tumors. The specimens were received in histology lab. After the gross examination, small biopsies were submitted entirely. Resection specimens were grossed according to standard protocols as per College of American Pathologists (CAP) guidelines. After submission of resection margins, representative sections were submitted from the tumor (one section per centimeter of tumor). Tumors smaller than 2 cm were submitted entirely. Immunohistochemical stains, pan-cytokeratin, synaptophysin, chromogranin A, and Ki67, were applied to selected paraffin-embedded blocks of all cases. Slides of all cases were retrieved and reexamined for tumor grade and differentiated by experienced histopathologists. New sections were performed from tissue blocks where necessary.

Morphologically WDNETs displayed characteristic organoid architectural patterns, including nests, cords, ribbons, and rosette formation. Cytologically, these tumors displayed a monomorphic population of cells with round to oval nuclei, coarse or stippled (salt-and-pepper-like) chromatin with a granular cytoplasm.

WDNETS were graded numerically into G1 (low), G2 (intermediate), and G3 (high) grades on the basis of the number of mitoses per 2 mm² and Ki67 proliferative index [6]. G1 tumors had less than two mitoses per 2 mm² and a Ki67 index of less than 3%. G2 tumors had 2-20 mitoses per 2 mm² and a Ki67 index between 3% and 20%. G3 tumors had more than 20 mitoses per 2 mm² and a Ki67 index of more than 20% (Figures 1-3).

(C): 400x magnification (H&E-staining) showing tumor cells with mild nuclear atypia and stippled coarse chromatin. (D): Pancytokeratin (CKAE1/AE3)-staining showing strong diffuse positivity. (E): Synaptophysin immunostaining depicting diffuse positivity. (F): Ki67 immunostaining showing less than 2% proliferative index; occasional cells show nuclear positivity (arrow).

H&E: Hematoxylin and eosin.

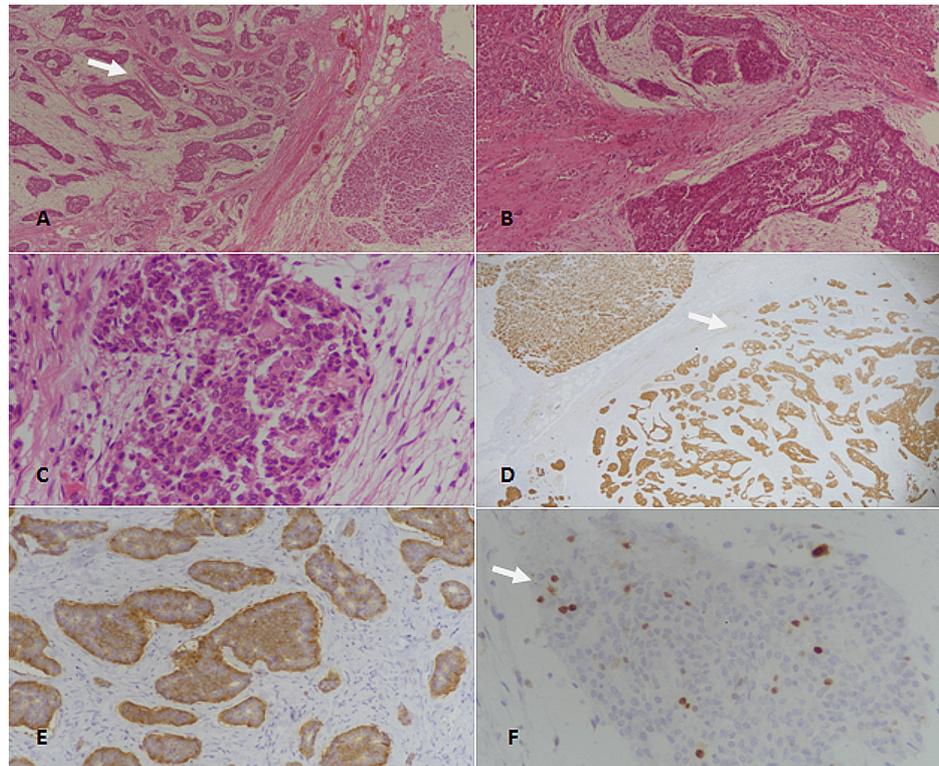

FIGURE 2: Well-differentiated neuroendocrine tumor (WDNET), grade 2 of the pancreas. (A): H&E-stained section at 40x magnification showing clusters of neoplastic neuroendocrine cells (arrow). (B): H&E-stained section at 100x magnification revealing neuroendocrine tumor with nested architecture. (C): 400x magnification (H&E-staining) showing tumor cells with moderate nuclear atypia and stippled coarse chromatin. (D): Pancytokeratin (CKAE1/AE3)-staining showing diffuse positivity (arrow) in tumor cells. (E): Synaptophysin immunostaining depicting diffuse positivity in tumor cells. (F): Ki67 immunostaining showing 5% proliferative index; nuclear positivity is seen in few tumor cells (arrow).

H&E: Hematoxylin and eosin.

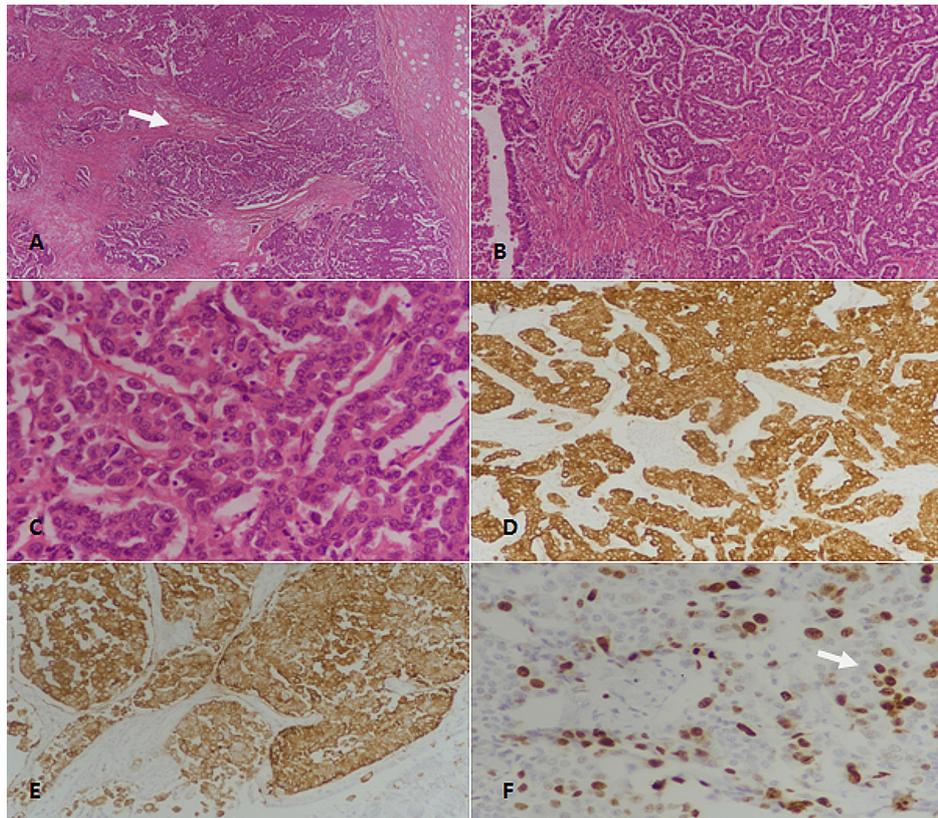

FIGURE 3: Well-differentiated neuroendocrine tumor (WDNET), grade 3. (A): H&E-stained section at 40x magnification showing nests and trabeculae of tumor cells (arrow). (B): H&E-stained section at 100x magnification revealing neuroendocrine tumor with organoid architecture. (C): 400x magnification (H&E-staining) showing tumor cells with moderate to marked nuclear atypia and coarse chromatin. (D): Pancytokeratin (CKAE1/AE3)-staining showing strong diffuse positivity. (E): Synaptophysin immunostaining depicting diffuse positivity. (F): Ki67 immunostaining showing more than 20% proliferative index; some tumor cells show nuclear positivity (arrow).

H&E: Hematoxylin and eosin.

PDNECs were characterized by a sheet-like architecture. Cytologically, the cells are more atypical than WDNETs (Figure 4).

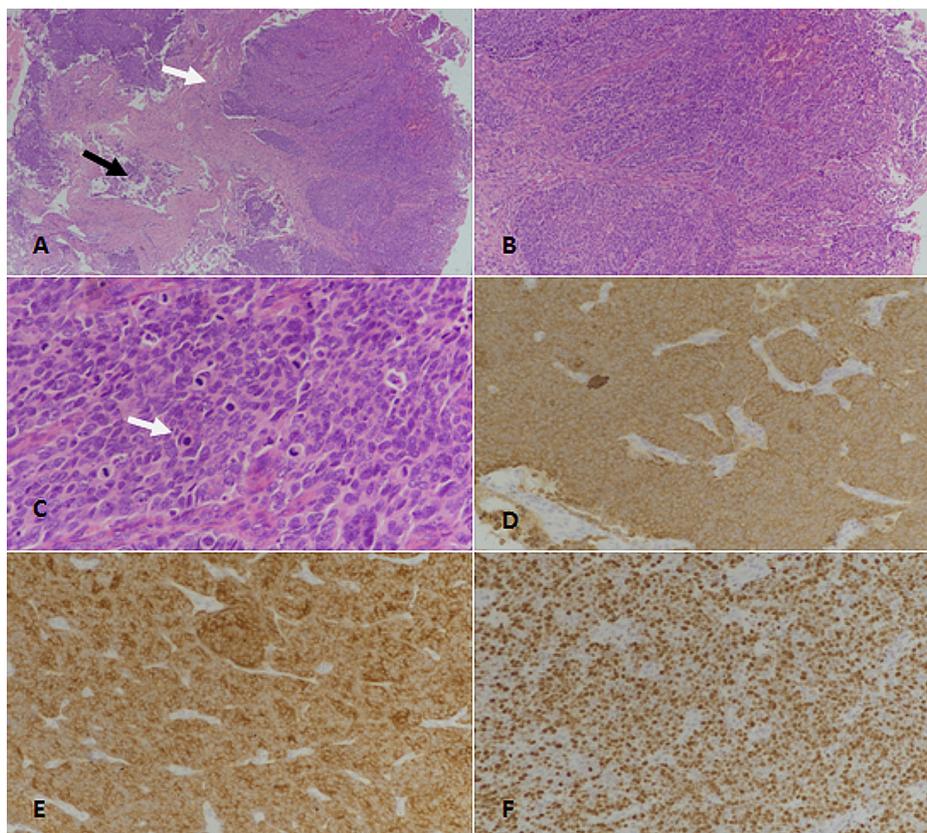

FIGURE 4: Poorly differentiated neuroendocrine carcinoma (PDNEC). (A): H&E-stained section at 40x magnification showing sheets of tumor cells (white arrow). Areas of necrosis are also evident (black arrow). (B): H&E-stained section at 100x magnification revealing neuroendocrine carcinoma with sheet-like architecture. (C): 400x magnification (H&E-staining) showing tumor cells with marked nuclear atypia and frequent mitoses (white arrow). (D): Pancytokeratin (CKAE1/AE3)-staining showing strong diffuse positivity. (E): Synaptophysin immunostaining depicting diffuse positivity. (F): Ki67 immunostaining showing approximately 80% proliferative index.

H&E: Hematoxylin and eosin.

Data analysis was performed using Statistical Package for Social Sciences (Version 26.0, IBM Inc., Armonk, USA). Chi-square, Fisher exact test, and independent t-test were used to check the association. P values ≤ 0.05 were considered significant.

Results

Our results showed that the mean age of patients was 46.8 ± 17.1 years, and 62.3% belonged to male gender. Majority of the NENs were GI tract origin (86.9%). The most common site of tumor in gastroenteropancreatic tract was the small bowel (31.1%), followed by the stomach (26.2%); 95.1% of the tumors were WDNETs, out of which most common grade was G2. Six cases were of PDNEC, out of which two were SCNEC and four were LCNEC. The mean Ki67 index was 15.8 ± 23.8 (Table 1).

WDNET, Well-differentiated neuroendocrine tumor; PDNEC, poorly differentiated neuroendocrine carcinoma.

Table 3 shows the association of clinicopathological features of WDNETs with tumor grade. There was a significant difference in terms of age. Grade 3 WDNETs were noted to have an older mean age than grades 1 and 2 WDNETs. Ten out of 102 (9.8%) WDNETs of GI tract were grade 3, compared with four out of 14 (28.5%) of pancreatobiliary tract. Grade 2 and 3 WDNETs had a larger tumor size than grade 1 tumors. Grade 3 WDNETs also had a higher tumor (T) stage than grade 1 and 2 tumors; however, the results were not statistically significant.

WNET, Well-differentiated neuroendocrine tumor; PDNEC, poorly differentiated neuroendocrine carcinoma.

Discussion

In our study, we studied the clinicopathological features of primary neuroendocrine tumors of GI/pancreatobiliary tract with emphasis on high-grade WNETs. WNETs were far more frequent than PDNECs, especially in GI tract. We found that the small bowel was the most common site for primary WNETs. We also noted that grade 3 WNETs were significantly more common in the pancreatobiliary tract than GI tract and were associated with older mean age. We also noted that PDNECs had a higher proliferative index and mean age than grade 3 WNETs; the finding was not statistically significant owing to the small number of cases in the PDNEC category.

The WNETs of the digestive tract were previously classified as grade 1 and grade 2 tumors with a criterion of mitoses and Ki67 index being <2 mitoses/2 mm² and <3% Ki67 index for G1 NETs as well as 2-20 mitoses/2 mm² and 3%-20% Ki67 index for G2 NETs. Tumors that exceeded the mitotic cutoff of more than 20 mitosis/2 mm² or Ki67 index of more than 20% were classified as NECs. The recent amendment introduced WNET grade 3 into the classification. These tumors retain the morphological features of WNETs, i.e., organoid histological patterns with nests, cords, trabeculae, ribbons, and rosette formation; however, these tumors have more than 20 mitoses/2 mm² or Ki67 index of more than 20%. The need for this introduction was based on the differences in the pathogenesis of WNET and PDNEC that impacted the treatment course and clinical outcomes [7]. Moreover, many studies have shown that differentiation status is the most important prognostic factor in determining the clinical course of NENs regardless of their primary site or stage [8,9]. Ishido et al. showed that small bowel tumors that were less than 1 cm had a risk of muscularis

propria and lymphovascular invasion along with lymph node metastasis [10].

Grade 3 WDNets are considered prognostically worse than PDNECs. A study revealed that high-grade component was noted in 48% of WDNets of GI/pancreatobiliary tract with a median disease-free survival (DFS) of 55 months that was significantly better than PDNECs (median DFS = 11 months) [7]. Similarly, another study revealed 12.9 months overall survival for GI/pancreatobiliary tract PDNECs [11]. Therefore, it is essential to distinguish grade 3 WDNets from PDNECs.

Immunohistochemical studies are useful in determining the site of origin of NENs. While CK7 and CK20 stains are of limited use in this context, TTF1 and CDX2 are helpful in differentiating lung-origin NENs from GI-origin NENs.

To date, few studies have compared the clinicopathological features of high-grade (grade 3) WDNets from low-grade (1-2) NETs. While the sample size of our study was small and we compared the results retrospectively, we found significant associations of grade 3 WDNets in terms of age and location. However, follow-up data were not available; therefore, we could not compare the survival or disease recurrence between different grades of WDNets. Therefore, based on our results, large-scale prospective trials are warranted to validate our findings and to further reveal the differences between these tumors in terms of recurrence and survival.

Conclusions

NENs are heterogeneous in terms of disease origin and pathogenesis. Grade 3 WDNets are recently described. In our study, we noted that grade 3 WDNets were more common in the pancreatobiliary tract than GI tract. Moreover, grade 3 WDNets were associated with older mean age than low-grade WDNets. Further studies are needed to explore more differences between WDNets of different grades in terms of survival and disease recurrences in our population. In addition, biological differences between WDNets of different grades should be explored for better patient management. For a pathological perspective, it is extremely important to understand the morphological differences between high-grade WDNets and PDNECs, as some recent studies have shown a significant difference in the survival between these two groups of NENs, despite comparable proliferative index.
